

## Cold winter day

During a cold winter day, wind at 40 km/h is blowing parallel to a 4-m-high and 8-m-long wall of a house. If the air outside is at 5 °C and the surface temperature of the wall is 15 °C, determine the rate of heat loss from that wall by convection.

## Moving train

The top surface of the passenger car of a train moving at a velocity of 80 km/h is 3 m wide and 10 m long. The top surface is absorbing solar radiation at a rate of  $250 \text{ W/m}^2$ , and the temperature of the ambient air is  $20^\circ\text{C}$ . Assuming the roof of the car to be perfectly insulated and the radiation heat exchange with the surroundings to be small relative to convection, determine the equilibrium temperature of the top surface of the car.

## Cooling a transformer

A transformer that is 15 cm long, 6.5 cm wide and 7 cm high is to be cooled by attaching a 15 cm x 6.5-cm-wide polished aluminum heat sink (emissivity = 0.05) to its top surface. The heat sink has ten fins, which are 5 mm high, 2 mm thick and 15 cm long. A fan blows air at 20°C parallel to the passages between the fins. The heat sink is to dissipate 15 W of heat and the base temperature of the heat sink is not to exceed 60 °C. Assuming the fins and the base plate to be nearly isothermal and the radiation heat transfer to be negligible, determine the minimum free-stream velocity the fan needs to supply to avoid overheating. Assume the flow is laminar over the entire finned surface of the transformer.

## Cylindrical rod

A heated, long cylindrical rod is placed in a cross flow of air at  $20^{\circ}\text{C}$  and 1 bar with velocity of 10 m/s. the rod has a diameter of 5 mm and its surface has an emissivity of 0.95. If the surrounding temperature is  $20^{\circ}\text{C}$  and the heat flux dissipated from the rod is  $16000\text{ W/m}^2$ , determine the surface temperature of the rod. Evaluate the air properties at  $80^{\circ}\text{C}$ .

## Hot stainless ball

A stainless steel ball ( $\rho = 8055 \text{ [kg/m}^3\text{]}$ ,  $c_p = 480 \text{ [J/kgK]}$ ) of diameter  $D = 10 \text{ cm}$  is removed from the oven at a uniform temperature of  $250^\circ\text{C}$ . The ball is then subjected to the flow of air at 1 bar pressure and  $20^\circ\text{C}$  with a velocity of 8 m/s. The surface temperature of the ball eventually drops to  $150^\circ\text{C}$ . Determine the average convection heat transfer coefficient during this cooling process and estimate how long this process has taken.

**Hint:** Use  $\eta_\infty = 1.872 \cdot 10^{-5} \text{ kg/ms}$  and  $\eta_w = 2.934 \cdot 10^{-5} \text{ kg/ms}$

## Cooled lamp

Consider a 15-cm-diameter 50-W lightbulb cooled by a fan that blows air at 20°C to the bulb at a velocity of 3 m/s. The surrounding surfaces are also at 20°C. Assuming 10 percent of the energy passes through the glass bulb as light with negligible absorption and the rest of the energy is absorbed and dissipated by the bulb itself, determine the equilibrium temperature of the glass bulb.

**Hint:** Use  $\eta_{\infty} = 1.872 \cdot 10^{-5} \text{ kg/ms}$  and  $\eta_w = 2.181 \cdot 10^{-5} \text{ kg/ms}$

## Water heater

Water at  $15^\circ\text{C}$  is to be heated to  $65^\circ\text{C}$  by passing it over a bundle of 4-m-long, 1-cm-diameter resistance heater rods maintained at  $90^\circ\text{C}$ . Water approaches the heater rod bundle in normal direction at a velocity of  $1.2\text{ m/s}$ . The rods are arranged in-line with transverse and longitudinal pitches of  $t_t = 3\text{ cm}$  and  $t_l = 4\text{ cm}$ . Determine the number of tube rows  $N_L$  in the flow direction needed to achieve the indicated temperature rise
